Lecture 7a: Efron Stein inequality

Purnamrita Sarkar Department of Statistics and Data Science The University of Texas at Austin

# **Efron Stein inequality**

- Consider n independent random variables in some metric space  $\mathcal{X}$ .
- Consider a function  $g: \mathcal{X}^n \to \mathbb{R}$
- Let  $Z := g(X_1, ..., X_n)$
- We are interested in computing  $var(g(X_1,...,X_n))$
- Define  $E_i(Z) = E[Z|X_{1:i-1}, X_{i+1:n}]$

# An upper bound

#### **Theorem**

$$var(Z) \le \sum_{i=1}^{n} E[Z - E_{i}[Z]]^{2}$$

- Note that the RHS can be thought of sum of expectation of conditional variances
- Since  $var(X) \le E[(X a)^2]$ , we also have:

$$\operatorname{var}(Z) \leq \sum_{i=1}^{n} E \left[ Z - Z_{i} \right]^{2},$$

where 
$$Z_i = g(X_1, ..., X_{i-1}, X_{i+1}, ..., X_n)$$

# An upper bound

#### **Theorem**

$$var(Z) \le \sum_{i=1}^{n} E[Z - E_{i}[Z]]^{2}$$

#### Proof.

- For two arbitrary bounded random variables X, Y, we have: E[XY] = E[E[XY|Y]] = E[YE[X|Y]]
- Let V := Z E[Z]
- Let  $V_i := E[Z|X_{1:i}] E[Z|X_{1:i-1}]$
- Clearly  $V = \sum_{i} V_{i}$

## **Proof continued**

$$var(Z) = E\left[\sum_{i} V_{i}\right]^{2} \tag{1}$$

$$= \sum_{i} E[V_i^2] + 2 \sum_{i < j} E[V_i V_j] = \sum_{i} E[V_i^2]$$
 (2)

• Why is the last step true? For i > j

$$E[V_i V_j] = E[E[V_i V_j | X_1, \dots, X_j]]$$
  
=  $E[V_j E[V_i | X_1, \dots, X_j]] = 0$ 

## Proof cont.

• Note that for three independent random variables X, Y, Z

$$E[g(X, Y, Z)|X] = E[E[g(X, Y, Z)|X, Z]|X, Y]$$

$$LHS = \int_{y,z} g(x,y,z) f(y,z|x) dy dz = \int_{z} (\int_{y} g(x,y,z) f(y|x,z) dy) f(z|x) dz$$

$$= \int_{z} E[g(X,Y,Z)|X,Z] f(z|x) dz$$

$$\stackrel{independence}{=} \int_{z} E[g(X,Y,Z)|X,Z] f(z|x,y) dz$$

$$= E[E[g(X,Y,Z)|X,Z]|X,Y]$$

## Proof cont.

 $V_{i}^{2} = (E[Z|X_{1:i}] - E[Z|X_{1:i-1}])^{2}$   $= (E[Z|X_{1:i}] - E[Z|X_{1:i-1}])^{2}$   $= (E[E[Z|X_{1:n}]|X_{1:i}] - E[E[Z|X_{1:i-1}, X_{i+1:n}]|X_{1:i}])^{2}$   $= (E[E[Z|X_{1:n}] - E[Z|X_{1:i-1}, X_{i+1:n}]|X_{1:i}])^{2}$   $= (E[Z - E_{i}Z|X_{1:i}])^{2}$ 

 $< E[(Z - E; Z)^2 | X_{1:}]$ 

 $E[V_i^2] < E[(Z - E_i Z)^2]$ 

# The Efron Stein inequality

#### Theorem

Let  $X'_1, \ldots X'_n$  denote an independent copy of  $X_1, \ldots, X_n$ . Let  $Z'_i = g(X_{1:i-1}, X'_i, X_{i+1:n})$ . We have:

$$var(Z) \leq \frac{1}{2} \sum_{i} E[(Z - Z_i')^2].$$

#### Proof.

- If X, Y are iid,  $var(X) = \frac{E[X Y]^2}{2}$
- Conditioned on  $X_{1:i-1}, X_{i+1:n}, Z$  and  $Z'_i$  are independent and so

$$E_{i}[Z - E_{i}[Z]]^{2} = \frac{E_{i}[Z - Z_{i}']^{2}}{2}$$

$$var(Z) \leq \sum_{i=1}^{n} E[Z - E_{i}[Z]]^{2} = \sum_{i=1}^{n} \frac{E[E_{i}[Z - Z_{i}']^{2}]}{2}$$

### Remarks

- For  $g(X_1, ..., X_n) = \sum_i X_i$  we have an equality.
- So in some sense, sums of independent random variables are the least concentrated functions
- Consider a function with the Bounded Difference property, i.e.

$$\sup_{x_{1:n},x_i' \in \mathcal{X}} |g(x_1,\ldots,x_n) - g(x_{1:i-1}x_i'x_{i+1:n})| \le c_i$$

• We have:

$$\operatorname{var}(g(X)) \le \frac{1}{2} \sum_{i} c_i^2$$

Q

# **Example: longest common subsequence**

Let  $X_1, \ldots, X_n$  and  $Y_1, \ldots, Y_n$  be two sequences of coin flips. Z is the length of the longest common subsequence.

$$Z = \max\{k: X_{i_1} = Y_{j_1}, \dots, X_{i_k} = Y_{j_k}\}$$

where  $1 \le i_1 < i_2 ...$  and  $1 \le j_1 < j_2 ...$ 

- It is well known that  $E[Z]/n \to \mu$  where  $\mu \in [0.757, 0.837]$ .
- If you change one bit of X, it can change Z by at most one, so,

$$var(Z) \leq n$$

• So Z concentrates around its mean.

## **Uniform deviation**

For 
$$X_1,\ldots,X_n$$
 iid random variables, let  $\hat{P}_n(A)=\frac{1}{n}\sum_i 1(X_i\in A)$  and  $P_n(A)=P(X_i\in A).$  We are interested in te quantity  $Z:=\sup_A |\hat{P}_n(A)-P_n(A)|$ 

- If we change one  $X_i$ , Z changes by 1/n at most.
- So  $var(Z) \le \frac{1}{2n}$  by the Efron Stein inequality.
- Can we do better?

# **Uniform deviation**

For  $X_1, \ldots, X_n$  iid random variables, let

$$Z = \sup_{f \in \mathcal{F}} \sum_{j} f(X_{j}).$$

For simplicity, assume  $Ef[X_i] = 0$ . We will show that the E/S inequality gives a much tighter upper bound that the one we just derived.

- $\operatorname{var}(Z) \leq \frac{1}{2} \sum_{i} E[(Z Z_i')^2]$
- Say f\* achieves the supremum for Z and f\* achieves the supremum for Z'<sub>i</sub>

$$f_*(X_i) - f_*(X_i') \le Z - Z_i' \le f^*(X_i) - f^*(X_i')$$

$$(Z - Z_i')^2 \le \max((f_*(X_i) - f_*(X_i'))^2, (f^*(X_i) - f^*(X_i'))^2)$$

$$\le \sup_{f \in \mathcal{F}} (f(X_i) - f(X_i'))^2$$

## **Uniform deviation**

$$\operatorname{var}(Z) \leq \frac{1}{2} \sum_{i} E \left[ \sup_{f \in \mathcal{F}} (f(X_{i}) - f(X_{i}'))^{2} \right]$$

$$\leq \sum_{i} E \left[ \sup_{f \in \mathcal{F}} (f(X_{i})^{2} + f(X_{i}')^{2}) \right]$$

$$\leq 2 \sum_{i} E \sup_{f \in \mathcal{F}} f(X_{i})^{2}$$

- (i) uses  $|2ab| \le a^2 + b^2$
- If  $f(X_i) \in [-1,1]$  we get  $var(Z) \leq 2n$
- But if the maximum variance of  $f(X_i)$  is small we have a significant improvement.

# Minimum of empirical loss

Consider a function class  $\mathcal{F}$  of binary valued functions on some space  $\mathcal{X}$ . Given an iid sample  $(X_i, Y_i) \in \mathcal{X} \times \{0, 1\}$ , for each  $f \in \mathcal{F}$  we define the empirical loss:

$$L_n(f) = \frac{1}{n} \sum_{i=1}^n \ell(f(X_i), Y_i)$$
 where  $\ell(y, y') = 1(y \neq y')$ 

Define the empirical loss as  $\hat{L} = \inf_{f \in \mathcal{F}} L_n(f)$ .

- Naive application of Efron Stein shows  $var(\hat{L}) \le 2/n$
- Is this enough?

# Minimum of empirical loss

- Let  $Z = n\hat{L}$
- Let  $Z_i = \min_{f \in \mathcal{F}} \left( \sum_{j \neq i} \ell(f(X_j), Y_j) + \ell(f(X_i'), Y_i') \right)$
- $\operatorname{var}(Z) \leq \frac{1}{2} \sum_{i} E[Z Z_{i}']^{2} = \sum_{i} E[(Z Z_{i}')^{2} 1(Z_{i}' > Z)]$
- Note that  $0 \ge (Z Z_i')1(Z_i' > Z) \ge (\ell(f^*(X_i), Y_i) \ell(f^*(X_i'), Y_i'))1(Z_i' > Z)$
- So  $(Z Z_i')^2 1(Z_i' > Z) \le (\ell(f^*(X_i), Y_i) \ell(f^*(X_i'), Y_i'))^2 1(Z_i' > Z) \le \ell(f^*(X_i'), Y_i') 1(\ell(f^*(X_i), Y_i) = 0)$
- So,  $E\sum_{i}(Z-Z_{i}')^{2}1(Z_{i}'>Z) \leq E\sum_{\ell(f^{*}(X_{i}),Y_{i})=0}E_{X_{i}',Y_{i}'}\ell(f^{*}(X_{i}'),Y_{i}') \leq nEL(f^{*})$
- Often you can show that  $EL(f^*) = E\hat{L} + O(n^{-1/2})$
- So  $\operatorname{var}(\hat{L}) \leq \frac{E\hat{L}}{n} + o(1)$

# **Self bounding functions**

#### **Definition**

A non-negative function  $g:\mathcal{X}^n \to \mathcal{R}$  has the self bounding property if there exist functions  $g_i:\mathcal{X}^{n-1} \to \mathcal{R}$  such that for all  $x_1,\ldots,x_n \in \mathcal{X}$  and  $i \in [n]$ ,

- $0 \le g(x_1, \ldots, x_n) g_i(x_{1:i-1}, x_{i+1:n}) \le 1$
- $\sum_{i} (g(x_1,...,x_n) g_i(x_{1:i-1},x_{i+1:n})) \leq g(x_1,...,x_n)$
- Clearly,  $\sum_{i} (g(x_{1:n}) g_i(x_{1:i-1}, x_{i+1:n}))^2 \le g(x_1, \dots, x_n) =: Z$
- Now Theorem 1 gives:

$$var(Z) \le \sum_{i} E[(Z - E_{i}[Z])^{2}] \le \sum_{i} E[(Z - g_{i}(x_{1:i-1}, x_{i+1:n}))^{2}] \le E[g(x_{1:n})]$$

• So  $var(Z) \leq E[Z]$ 

# Concentration of self bounding functions

#### **Theorem**

Consider  $Z := g(X_1, ..., X_n)$  where  $X_1, ..., X_n$  are independent random variables. For all  $t \ge 0$ ,

$$P(Z \ge E[Z] + t) \le \exp\left(-\frac{t^2}{2(EZ + t/3)}\right)$$
  
 $P(Z \le E[Z] - t) \le \exp\left(-\frac{t^2}{2EZ}\right)$ 

# Relative Stability

- A sequence of non-negative random variables  $\{Z_n\}$  are said to be relatively stable if  $Z_n/E[Z_n] \stackrel{P}{\to} 1$
- If  $Z_n$  also satisfies the self bounding property,

$$P\left(\left|\frac{Z_n}{E[Z_n]} - 1\right| \ge \epsilon\right) \le \frac{\operatorname{var}(Z_n)}{\epsilon^2 E[Z_n]^2} \le \frac{1}{\epsilon^2 E[Z_n]}$$

• So as long as  $E[Z_n] \to \infty$ ,  $Z_n$  satisfies the relative stability condition

# **Example: empirical processes**

Consider a function class  $\mathcal{F}$  of functions in [0,1].  $Z:=\sup_{f\in\mathcal{F}}\sum_i f(X_i)$ . We show that Z is self bounding.

- Let  $Z_i := \sup_{f \in \mathcal{F}} \sum_{j \neq i} f(X_i)$
- Let  $f^*$  maximize Z and  $f_i$  maximize  $Z_i$
- We have  $0 \le f_i(X_i) \le Z Z_i \le f^*(X_i) \le 1$
- So  $\sum_{i} (Z Z_i) \leq \sum_{i} f^*(X_i) = Z$
- Hence  $var(Z) \le E[Z]$ , while a naive application of E-S will give us  $var(Z) \le n/2$

# Rademacher averages

Consider a function class  $\mathcal{F}$  of functions in [-1,1]. Let  $\{\epsilon_i\}_1^n$  denote n independent Rademacher variables independent of  $X_1,\ldots,X_n$ . The conditional Rademacher average is defined as

$$Z := E \left[ \sup_{f \in \mathcal{F}} \sum_{i} \epsilon_{i} f(X_{i}) | X_{1:n} \right]$$

Z has the self bounding property and so  $var(Z) \leq E[Z]$ .

• Define 
$$Z_i := E\left[\sup_{f \in \mathcal{F}} \sum_{j \neq i} \epsilon_j f(X_j) | X_{1:n}\right]$$

# Rademacher avg cont.

• Let  $f^*$  maximize Z and  $f_i$  maximize  $Z_i$ . Note that:

$$Z - Z_i \leq E[\epsilon_i f^*(X_i)|X_{1:n}] \leq 1$$

• On the other hand,

$$Z - Z_i \ge E[\epsilon_i f_i(X_i) | X_{1:n}] = 0$$

- The last step is true because ?
- So  $\sum_i (Z Z_i) \leq Z$
- Hence Z has the self-bounding property and has  $var(Z) \le E[Z]$
