SDS 384-11 PS #2, Spring 2022

Instructor: Purnamrita Sarkar*

Monday 2$^{\text{nd}}$ May, 2022

Exercise 1 (4 pts). *Remember Hoeffding's Lemma? We proved it with a weaker constant in class using a symmetrization type argument. Now we will prove the original version. Let X be a bounded r.v. in $[a, b]$ such that $E[X] = \mu$. Let $f(\lambda) = \log E[e^{\lambda(X-\mu)}]$. Show that $f''(\lambda) \leq (b-a)^2/4$. Now use the fundamental theorem of calculus to write $f(\lambda)$ in terms of $f''(\lambda)$ and finish the argument.*

[Rubric] 5 points. I think most people will use the short proof where you have the trick of exp(lambda(X-mu))/E[...] as a density. If anyone does in a more complicated but correct way give full score. I kind of am expecting everyone to get a full score on this, if they prove the correct outcome. Since not much avenue to go wrong.

Solution.
First we find $f''(\lambda)$

$$f''(\lambda) = \frac{d}{d\lambda}\frac{d}{d\lambda}\log E[e^{\lambda(X-\mu)}]$$

$$= \frac{d}{d\lambda}\left[\frac{1}{E[e^{\lambda(X-\mu)}]}E[(X-\mu)e^{\lambda(X-\mu)}]\right]$$

$$= \frac{E[(X-\mu)^2 e^{\lambda(X-\mu)}]}{E[e^{\lambda(X-\mu)}]} - \left(\frac{E[(X-\mu)e^{\lambda(X-\mu)}]}{E[e^{\lambda(X-\mu)}]}\right)^2.$$

Notice that $f''(\lambda)$ is simply the variance of $X-\mu$ with respect to the probability measure $\frac{e^{\lambda(X-\mu)}}{E[e^{\lambda(X-\mu)}]}P(X)$. We know that $E[(X-t)^2]$ is minimized when $t = E[X]$, thus

$$f''(\lambda) = \text{var}(X)$$
$$\leq E[(X - (b-a)/2)^2]$$
$$\leq \frac{(b-a)^2}{4}.$$

Now we will use the fundamental theorem of calculus to show that $f(\lambda) \leq \frac{\lambda^2(b-a)^2}{8}$. Note from the derivations above $f'(0) = f(0) = 0$

$$\int_0^\lambda \int_0^\nu f''(t)dtd\nu \leq \int_0^\lambda \int_0^\nu \frac{(b-a)^2}{4}dtd\nu$$
$$\int_0^\lambda f'(\nu)d\nu \leq \int_0^\lambda \frac{\nu(b-a)^2}{4}d\nu$$
$$f(\lambda) \leq \frac{\lambda^2(b-a)^2}{8}$$

Taking the exponent of both sides gives back Hoeffding's Lemma. $\square$

---

*Thanks to Matthew Faw, Brandon Carter for some of the solutions

Exercise 2. *Consider a r.v. X such that for all* $\lambda \in \Re$

$$M(\lambda) \triangleq E[e^{\lambda X}] \leq e^{\frac{\lambda^2 \sigma^2}{2} + \lambda \mu}$$

If you find anyone saying f(x)<g(x) implies f'(x)<g'(x) Take 2 points off from 5. Because that is a serious mistake and point to solutions.

   Prove that:

1. $\mathbb{E}[X] = \mu$.

   [Rubric] 2+2+1.

   Solution.
   Let $f(\lambda) = E[e^{\lambda X}]$ and let $g(\lambda) = e^{\lambda^2 \sigma^2/2 + \lambda \mu}$. We have $f(0) = g(0)$.

   $$f'(0) = \lim_{h \to 0} \frac{f(h) - f(0)}{h} \leq \lim_{h \to 0} \frac{g(h) - g(0)}{h} = g'(0)$$

   But we also have:

   $$f'(0) = \lim_{h \to 0} \frac{f(0) - f(-h)}{h} \geq \lim_{h \to 0} \frac{g(0) - g(-h)}{h} = g'(0)$$

   So $f'(0) = g'(0)$. So we have $E[X] = \mu$.

   $\square$

2. $\text{Var}(X) \leq \sigma^2$. *Again, if you see that the remainder term is $o(\lambda^2)$ w/o explanation, take 1/2 point off.*

   Solution.

   Let us denote

   $$M_c(\lambda) = \exp(-\lambda \mu) M(\lambda)$$
   $$= \mathbb{E}[\exp(\lambda(X - \mu))]$$

   and similarly,

   $$U_c(\lambda) = \exp(-\lambda \mu) U(\lambda)$$
   $$= \exp\left(\frac{\lambda^2 \sigma^2}{2}\right)$$

   Then, by construction, we have that $M_c(\lambda) \leq U_c(\lambda)$. Additionally, $M_c(0) = 1 = U_c(0)$, $M_c''(0) = \text{Var}(X)$, and $U_c''(0) = \sigma^2$. Therefore, we have that

   $$\text{Var}(X) = M_c''(0)$$
   $$= \lim_{\varepsilon \to 0} \frac{M_c(\varepsilon) + M_c(-\varepsilon) - 2M_c(0)}{\varepsilon^2}$$
   $$= \lim_{\varepsilon \to 0} \frac{M_c(\varepsilon) + M_c(-\varepsilon) - 2U_c(0)}{\varepsilon^2}$$
   $$\leq \lim_{\varepsilon \to 0} \frac{U_c(\varepsilon) + U_c(-\varepsilon) - 2U_c(0)}{\varepsilon^2}$$
   $$= U_c''(0)$$
   $$= \sigma^2$$

which establishes the desired inequality.

□

3. *If the smallest value of σ satisfying the above equation is chosen, is it true that* $\text{Var}(X) = \sigma^2$? *Prove or give a counter example. Any correct answer is fine.*

Solution.
We give a counterexample to establish that $\sigma^2 \neq \text{Var}(X)$. Consider $X \sim \text{Bern}(p)$. Then, assuming that $\sigma^2 = p(1-p) = \text{Var}(X)$, we have that

$$
\begin{aligned}
\mathbb{E}\left[\exp\left(\lambda\left(X-p\right)\right)\right] &= p\exp(\lambda(1-p)) + (1-p)\exp(-\lambda p) \\
&= \exp(\lambda(1-p))\left(p + (1-p)\exp(-\lambda)\right) \\
&\leq \exp\left(\frac{\lambda^2 p(1-p)}{2}\right) \qquad\qquad \text{by assumed subG bound}
\end{aligned}
$$

$$
\implies p + (1-p)\exp(-\lambda) \leq \exp\left(\lambda(1-p)\left(\frac{\lambda p}{2} - 1\right)\right) \tag{1}
$$

However, by choosing, for example, $\lambda = \frac{1}{4}$ and $p = \frac{1}{16}$, one can check that

$$
p + (1-p)\exp(-\lambda) - \exp\left(\lambda(1-p)\left(\frac{\lambda p}{2} - 1\right)\right) \approx 0.0001 > 0
$$

which is a *contradiction* of inequality (1). Therefore, we cannot always take $\sigma^2 = \text{Var}(X)$.

□

Exercise 3. *Given a positive semidefinite matrix $Q \in \mathbb{R}^{n \times n}$, consider $Z = \sum_{i,j} Q_{ij} X_i X_j$. When $X_i \sim N(0,1)$, prove the Hanson-Wright inequality.*

$$
P\left(Z \geq trace(Q) + t\right) \leq \exp\left(-\min\left\{c_1 t/\|Q\|_{op}, c_2 t^2/\|Q\|_F^2\right\}\right),
$$

where $\|Q\|_{op}$ and $\|Q\|_F$ denote the operator and frobenius norms respectively. Hint: The rotation-invariance of the Gaussian distribution and sub-exponential nature of χ^2-variables could be useful. Again, I think if you get the answer, typically you should be right. Just check to make sure everyone understand what a frobenius norm/operator norm means.

Solution.
Observe that since Q is positive semidefinite, by the spectral theorem, we may decompose Q as

$$
Q = V\Lambda V^T,
$$

where $\Lambda = \text{diag}(\lambda_1, \ldots, \lambda_n)$, where $\lambda_i \geq 0$ is the ith largest eigenvalue of Q, and where V is an orthogonal matrix whose ith column vector is a unit eigenvector corresponding to λ_i.

Take $X \sim \mathcal{N}(\mathbf{0}, I_n)$, where I_n is the $n \times n$ identity matrix. Thus, by the linear transformation property of the normal distribution, we have that $Y = V^T X \sim \mathcal{N}(\mathbf{0}, \underbrace{V^T V}_{=I_n \text{ since } V \text{ is orthogonal}})$.

Therefore, we have that

$$
\begin{aligned}
Z = X^T Q X \\
= X^T V \Lambda V^T X \\
= Y^T \Lambda Y \\
= \sum_{i=1}^{n} \lambda_i Y_i^2
\end{aligned}
$$

Now, each $Y_i^2 \overset{i.i.d}{\sim} \chi_1^2$. Thus,

$$
\begin{aligned}
\mathbb{E}[Z] = \sum_{i=1}^{n} \lambda_i \underbrace{\mathbb{E}[Y_i^2]}_{=1} \\
= \sum_{i=1}^{n} \lambda_i \\
= \mathrm{trace}(Q)
\end{aligned}
$$

Now, following the same arguments used in class to obtain the subexponential parameters for χ^2 random variables, we have that $Z_i = \lambda_i Y_i^2$ is $(\nu_i = 2\lambda_i, b_i = 4\lambda_i)$-subexponential, and thus, by concentration of subexponential r.v.'s, we have that

$$
\mathbb{P}(Z_i - \mathbb{E}[Z_i] \geq t) \leq \begin{cases} \exp\left(-\frac{t^2}{8\lambda_i^2}\right) & \text{if } 0 \leq t \leq \frac{4\lambda_i^2}{4\lambda_i} = \lambda_i \\ \exp\left(-\frac{t}{8\lambda_i}\right) & \text{if } t > \lambda_i \end{cases}
$$

Now, we have that Z is $(\sqrt{n}\nu_*, b_*)$-subexponential, where

$$
\nu_*^2 = \frac{1}{n}\sum_i \nu_i^2 = \frac{4}{n}\sum_i \lambda_i^2 = \frac{4}{n}\|Q\|_F^2
$$

$$
b_* = \max_k b_k = 4\lambda_1 = 4\|Q\|_{op}
$$

and so

$$
\mathbb{P}(Z - \mathrm{trace}(Q) \geq t) \leq \begin{cases} \exp\left(-\frac{t^2}{8\|Q\|_F^2}\right) & \text{if } 0 \leq t \leq \frac{\|Q\|_F^2}{\|Q\|_{op}} \\ \exp\left(-\frac{t}{8\|Q\|_{op}}\right) & \text{if } t > \frac{\|Q\|_F^2}{\|Q\|_{op}} \end{cases}
$$

as desired. $\qquad\square$

Exercise 4. *We will prove properties of subgaussian random variables here. Prove that:*

1. *Moments of a mean zero subgaussian r.v. X with variance proxy σ^2 satisfy:*

$$
E[|X^k|] \leq k 2^{k/2} \sigma^k \Gamma(k/2), \tag{2}
$$

   where Γ is the gamma function. Rubric: (1+2+2) For the first part, full score even if there are typos/minor mistakes if they arrive at the correct bound.

4

Solution.

We have that, by the Subgaussian assumption,

$$\mathbb{E}[|X|^k] = \int_0^\infty \mathbb{P}(|X|^k > t)dt$$

$$= \int_0^\infty \mathbb{P}(|X| > t^{1/k})dt$$

$$\leq 2\int_0^\infty \exp\left(-\frac{t^2}{2\sigma^2}\right)dt$$

Now, recalling that

$$\Gamma(z) = \int_0^\infty t^{z-1}\exp(-t)dt,$$

we may perform the change of variables $t = ax^b$ to obtain:

$$\Gamma(z) = \int_0^\infty a^{z-1}x^{bz-b}\exp(-ax^b)abx^{b-1}dx$$

$$= a^z b \int_0^\infty x^{bz-1}\exp(-ax^b)dx$$

Thus,

$$\Gamma\left(\frac{1}{b}\right) = a^{\frac{1}{b}}b\int_0^\infty \exp(-ax^b)dx$$

Now, choosing $a = \frac{1}{2\sigma^2}$ and $b = \frac{2}{k}$, we combine our results to obtain:

$$\mathbb{E}[|X|^k] \leq 2\int_0^\infty \exp\left(-\frac{t^2}{2\sigma^2}\right)dt$$

$$= \frac{2}{a^{\frac{1}{b}}b}\Gamma\left(\frac{1}{b}\right)$$

$$= \frac{2}{\left(\frac{1}{2\sigma^2}\right)^{\frac{k}{2}}\frac{2}{k}}\Gamma\left(\frac{k}{2}\right)$$

$$= k2^{k/2}\sigma^k\Gamma\left(\frac{k}{2}\right)$$

as desired. $\qquad\square$

2. *If X is a mean 0 subgaussian r.v. with variance proxy σ^2, prove that, $X^2 - E[X^2]$ is a subexponential $(c_1\sigma^2, c_2\sigma^2)$ (we are using the (ν, b) parametrization of subexponentials we did in class, so ν^2 is the variance proxy). Here c_1, c_2 are positive constants.*

Many people will use $E[(X^2 - [EX]^2)^k] \leq E[X^{2k}]$. This is wrong. 1 pt off for this. For those who use the definition of sub-exponentiality from scratch, if they assume $t > 0$, take 1/2 point off. See the alternative solution here.

I am going to give two different solutions here. And point out common mistakes you may make. The first uses Bernstein's moment condition. In class we did a

5

very easy bounded random variable example to show it is subexponential since it satisfies the bernstein m.c. Here is a far less trivial example of its use. The second solution gets to the answer through the definition of sub-exp r.v.s as we saw in class.

Solution.
Here, we wish to apply the Bernstein condition. Observe that

$$\left| \mathbb{E}(X^2 - \mathbb{E}X^2)^k \right|$$
$$\leq \mathbb{E}\left|X^2 - \mathbb{E}X^2\right|^k \qquad\qquad \text{Jensen's}$$
$$= \mathbb{E}\left(\left|X^2 - \mathbb{E}X^2\right|^k \mathbb{1}\{X^2 \geq \mathbb{E}X^2\}\right) + \mathbb{E}\left(\left|X^2 - \mathbb{E}X^2\right|^k \mathbb{1}\{X^2 < \mathbb{E}X^2\}\right)$$

Now, observe that, almost surely,

$$|X^2 - \mathbb{E}X^2|^k \mathbb{1}\{X^2 \geq \mathbb{E}X^2\} \leq |X^2|^k \mathbb{1}\{X^2 \geq \mathbb{E}X^2\} \qquad \text{since } \mathbb{E}X^2 \geq 0$$
$$\leq |X|^{2k} \qquad\qquad\qquad \text{since } \mathbb{1}\{\cdot\} \leq 1 \text{ a.s.}$$

and similarly,

$$|X^2 - \mathbb{E}X^2|^k \mathbb{1}\{X^2 < \mathbb{E}X^2\} \leq |\mathbb{E}X^2|^k \mathbb{1}\{X^2 < \mathbb{E}X^2\} \quad \text{since } X^2 \geq 0 \text{ a.s.}$$
$$\leq |\mathbb{E}X^2|^k \qquad\qquad \text{since } \mathbb{1}\{\cdot\} \leq 1 \text{ a.s.}$$
$$\leq \mathbb{E}|X|^{2k} \qquad\qquad \text{by Jensen's, since } |\cdot|^k \text{ is convex}$$

Note the treatment above. Many of you may bound $E[(X^2 - [EX]^2)^k] \leq E[X^{2k}]$. This is incorrect, because $|X^2 - E[X^2]| \leq \max(X^2, E[X^2])$. I am gong to take a point off for this, just so that this sticks in our minds.

Finally, note that

$$\text{Var}(X^2) \leq \mathbb{E}X^4$$
$$\leq 4 \cdot 2^2 \sigma^4 \Gamma(2)$$
$$= 2^4 \sigma^4$$
$$< 2^5 \sigma^4$$

Combining these bounds, we have that

$$\left| \mathbb{E}(X^2 - \mathbb{E}X^2)^k \right| \leq 2\mathbb{E}|X|^{2k}$$
$$\leq 4k2^k \sigma^{2k} \underbrace{\Gamma(k)}_{=(k-1)!} \qquad\qquad \text{by the previous exercise}$$
$$= \frac{1}{2}k!2^5 \sigma^4 \left(2\sigma^2\right)^{k-2}$$

Therefore, by the Bernstein condition, we have that X^2 is subexponential with paratmeters $(\nu = 8\sigma^2, b = 4\sigma^2)$, as desired.

□

Solution.

Now we will prove the subexponentiality using the MGF. Note that we have $E[X^2] \le \sigma^2$.

$$E[\exp(\lambda(X^2 - E[X^2]))] \le \exp(-\lambda E[X^2]) E[\exp(\lambda X^2)]$$

$$= \exp(-\lambda E[X^2]) \left(1 + \lambda E[X^2] + \sum_{k \ge 2} \lambda^k \frac{E[X^{2k}]}{k!}\right)$$

$$= \exp(-\lambda E[X^2]) \left(1 + \lambda E[X^2] + 2 \sum_{k \ge 2} 2^k \sigma^{2k} |\lambda|^k\right)$$

(For $|\lambda| < 1/2\sigma^2$, we have) $= \underbrace{\exp(-\lambda E[X^2]) \left(1 + \lambda E[X^2]\right)}_{\text{This is} \le 1 \text{ since } \exp(x) \ge 1+x} + \frac{8\sigma^4 \lambda^2 \exp(-\lambda E[X^2])}{1 - 2\sigma^2 |\lambda|}$

(For $|\lambda| < 1/4\sigma^2$, we have) $\le 1 + \underbrace{16\sigma^4 \lambda^2 \exp(|\lambda| \sigma^2)}_{E[X^2] \le \sigma^2} \le 1 + \underbrace{16\sigma^4 \lambda^2 \exp(1/4)}_{|\lambda| \le 1/4\sigma^2}$

$$\le 1 + 2^5 \sigma^4 \lambda^2 \le \underbrace{\exp((4\sqrt{2}\sigma^2)^2 \lambda^2)}_{\exp(x) \ge 1+x}$$

So we have $X^2 - E[X^2]$ is sub exponential $(8\sigma^2, 4\sigma^2)$.

□

3. *Consider two independent mean zero subgaussian r.v.s X_1 and X_2 with variance proxies σ_1^2 and σ_2^2 respectively. Show that $X_1 X_2$ is a subexponential r.v. with parameters $(d_1 \sigma_1 \sigma_2, d_2 \sigma_1 \sigma_2)$. Here d_1, d_2 are positive constants.*

Again, here also, I think most people will get the right answer if they end up proving it. So full score unless you see obvious mistakes.

Solution.

Observe that,

$$\mathbb{E}[(X_1 X_2 - \mathbb{E}[X_1 X_2])^k] = \mathbb{E}[(X_1 X_2 - \mathbb{E}[X_1]\mathbb{E}[X_2])^k] \qquad \text{by independence}$$

$$= \mathbb{E}[(X_1 X_2)^k] \qquad \text{mean 0}$$

$$\le \mathbb{E}[|X_1 X_2|^k]$$

$$= \mathbb{E}[|X_1|^k]\mathbb{E}[|X_2|^k] \qquad \text{independence}$$

$$\le \left(k 2^{k/2} \sigma_1^k \Gamma\left(\frac{k}{2}\right)\right)\left(k 2^{k/2} \sigma_2^k \Gamma\left(\frac{k}{2}\right)\right) \qquad \text{by part 1}$$

$$= \left(k \Gamma\left(\frac{k}{2}\right)\right)^2 2^k (\sigma_1 \sigma_2)^2$$

Now, recall that, for k an odd integer,

$$\Gamma\left(\frac{k}{2}\right) = \Gamma\left(\left\lfloor\frac{k}{2}\right\rfloor + \frac{1}{2}\right)$$

$$= \sqrt{\pi}\frac{(2\lfloor\frac{k}{2}\rfloor)!}{4^{\lfloor k/2\rfloor}\lfloor k/2\rfloor!}$$

$$= \sqrt{\pi}\frac{2(k-1)!}{4^{k/2}\lfloor k/2\rfloor!}$$

Thus, we have that

$$\left(k\Gamma\left(\frac{k}{2}\right)\right)^2 = \pi k^2\frac{((k-1)!)^2}{4^k(\lfloor k/2\rfloor)^2} \tag{3}$$

$$\leq k! $$

$$\iff \pi k! \leq 4^k\lfloor k/2\rfloor! \tag{4}$$

Now, note that (3) is true for sufficiently large k. Similarly, when k is even,

$$\Gamma\left(\frac{k}{2}\right) = \left(\frac{k}{2}-1\right)!$$

so we have that

$$\left(k\Gamma\left(\frac{k}{2}\right)\right)^2 = k^2\left(\left(\frac{k}{2}-1\right)!\right)^2$$

$$\leq k! \tag{5}$$

$$\iff k\left(\frac{k}{2}-1\right)! \leq \prod_{i=1}^{\frac{k}{2}-1}(k-i)$$

$$\iff 1 \leq \frac{k-1}{k}\prod_{i=2}^{\frac{k}{2}-1}\frac{k-i}{\frac{k}{2}+1-i} \tag{6}$$

Observe that (5) is true for sufficiently large k. Therefore, there exists a universal constant C such that

$$\mathbb{E}[(X_1X_2-\mathbb{E}[X_1X_2])^k] = \left(k\Gamma\left(\frac{k}{2}\right)\right)^2 2^k(\sigma_1\sigma_2)^2$$

$$\leq Ck!2^k(\sigma_1\sigma_2)^k$$

$$\leq \frac{1}{2}k!(\sigma_1\sigma_2)^2(\tilde{C}\sigma_1\sigma_2)^k$$

For sufficiently large $\tilde{C}$. Therefore, since $\mathrm{Var}(X_1X_2) \leq \sigma_1^2\sigma_2^2$, by Bernstein's theorem, X_1X_2 is subexponential with parameters $(\nu = \sqrt{2}\sigma_1\sigma_2, b = 2\tilde{C}\sigma_1\sigma_2)$. This establishes the desired result.

$\square$
